Using the data samples collected in the energy range from 3.773 to 4.600 GeV with the BESIII detector at the BEPCII collider, we measure the dressed cross sections as a function of center-of-mass energy for  $e^+e^- \rightarrow K^+K^-\pi^+\pi^-(\pi^0)$ ,  $K^+K^-K^+K^-(\pi^0)$ ,  $\pi^+\pi^-\pi^+\pi^-(\pi^0)$ , and  $p\bar{p}\pi^+\pi^-(\pi^0)$ . The cross sections for

$e^+e^- \rightarrow K^+K^-K^+K^-\pi^0$ ,  $p\bar{p}\pi^+\pi^-(\pi^0)$  are the first measurements. Cross sections for the other five channels are much more precise than previous results in this energy region. We also search for charmonium and charmonium-like resonances, such as the  $Y(4230)$ , decaying into the same final states. We find evidence of the  $\psi(4040)$  decaying to  $\pi^+\pi^-\pi^+\pi^-\pi^0$  with a statistical significance of  $3.6\sigma$ . Upper limits are provided for other decays since no clear signals are observed.

## I. INTRODUCTION

The energy region above open-charm threshold provides a place to test and develop quantum chromodynamics (QCD). In the past decade, a series of charmonium-like states [1] were observed, such as the  $Y(4260)$  state discovered by the *BABAR* collaboration through the initial-state radiation (ISR) process  $\gamma_{\text{ISR}}\pi^+\pi^-J/\psi$  [2], and confirmed by CLEO [3], Belle [4] and BESIII [5] in the same process. A recent precise measurement of  $e^+e^- \rightarrow \pi^+\pi^-J/\psi$  [6] shows that the  $Y(4260)$  consists of two resonances; the narrower resonance at lower mass is called  $Y(4230)$ . The  $Y(4230)$  has also been reported by BESIII in the study of the  $e^+e^- \rightarrow \omega\chi_{c0}$  [7],  $\pi^+\pi^-h_c$  [8], and  $\pi^+D^0D^{*-}$  [9] cross sections.

Contrary to the conventional charmonium states, the  $Y(4230)$  strongly couples to  $\pi\pi J/\psi$  [6,9]. This is also true for other  $Y$  states, e.g.  $Y(4360)$  and  $Y(4660)$ . The discoveries of those exotic particles have prompted further investigations of the center-of-mass (c.m.) energy-dependent cross sections [10]. To explore the nature of these exotic particles, a variety of decay modes have been studied, such as open-charm processes [ $D^{(*)}\bar{D}^{(*)}$  [11–14],  $D^{(*)}\bar{D}^{(*)}\pi$  [13,15],  $D\bar{D}_2^{*}(2460)$  [16] and  $D_s^{(*)+}D_s^{(*)-}$  [13,17]], and transitions to other charmonium states [ $\pi^+\pi^-J/\psi$  [18],  $\pi^0\pi^0J/\psi$  [19],  $\eta J/\psi$  [20],  $\pi^+\pi^-h_c$  [21],  $\pi^+\pi^-\psi(3686)$  [22] and  $\omega\chi_{c0}$  [23]]. Many light hadron final states ( $K^+K^-\pi^+\pi^-$  [24,25],  $K^+K^-K^+K^-$  [24–26],  $\pi^+\pi^-\pi^+\pi^-$  [24],  $\phi f_0(980)$  [27],  $K^+K^-\eta$  [28],  $K^+K^-\pi^0$  [28],  $K_s^0K^\pm\pi^\mp$  [28],  $p\bar{p}$  [29], etc.) have also been studied. However, no light hadronic decays of the  $Y$  states or conventional charmonium resonances above 4 GeV have yet been observed [24–29]. The continued search for light hadron decays may help clarify the nature of exotic states and charmonium resonances [30,31].

To study charmonium and charmonium-like particles, the BESIII detector has collected the world's largest data samples in the energy region between 3.773 and 4.600 GeV. Based on those datasets, we analyze the dressed cross sections for the processes  $e^+e^- \rightarrow K^+K^-\pi^+\pi^-(\pi^0)$ ,  $K^+K^-K^+K^-(\pi^0)$ ,  $\pi^+\pi^-\pi^+\pi^-(\pi^0)$ , and  $p\bar{p}\pi^+\pi^-(\pi^0)$  and search for possible structures, such as charmonium or  $Y$  states, in the line shapes of the  $e^+e^-$  cross sections.

This paper is organized as follows. In Sec. II, we describe the BESIII detector. The data and Monte Carlo (MC) samples are introduced in Sec. III. In Sec. IV A, we describe the requirements for the selection of signal events. In

Sec. IV B, we present the measurement of the number of background events. The determination of  $e^0$  and  $\kappa$  are described in Secs. IV C and IV D, respectively. Section V discusses systematics uncertainties and a summary is presented in Sec. VI.

## II. DETECTOR

The BESIII detector is a magnetic spectrometer [32] located at the Beijing Electron Positron Collider (BEPCII) [33]. The cylindrical core of the BESIII detector consists of a helium-based multilayer drift chamber, a plastic scintillator time-of-flight system (TOF), and a CsI(Tl) electromagnetic calorimeter (EMC), which are all enclosed in a superconducting solenoidal magnet providing a 1.0 T magnetic field. The solenoid is supported by an octagonal flux-return yoke with resistive plate counter muon identifier modules interleaved with steel. The acceptance of charged particles and photons is 93% over  $4\pi$  solid angle. The charged-particle momentum resolution at 1 GeV/c is 0.5%, and the  $dE/dx$  resolution is 6% for the electrons from Bhabha scattering. The EMC measures photon energies with a resolution of 2.5% (5%) at 1 GeV in the barrel (end cap) region. The time resolution of the TOF barrel part is 68 ps, while that of the end cap part is 110 ps. The end cap TOF system was upgraded in 2015 with multigap resistive plate chamber technology, providing a time resolution of 60 ps [34]. This improvement affects 57% of the data used in this work.

## III. DATA AND MONTE CARLO SAMPLES

In this work, we analyzed the datasets taken at c.m. energies from 3.773 to 4.600 GeV. Measurements of c.m. energies and luminosities are described elsewhere [35,36].

The response of the BESIII detector is modeled with MC simulations using the software framework BOOST [37] based on GEANT4 [38], which includes the geometry and material description of the BESIII detectors, the detector response and digitization models, as well as a database that keeps track of the running conditions and the detector performance.

The signal MC samples at all c.m. energies are generated with a phase space (PHSP) model. The inclusive MC samples generated at different c.m. energies are used to study the potential backgrounds. The inclusive MC samples consist of the production of open charm processes, the ISR production of vector charmonium states, and the continuum

processes incorporated in KKMC [39]. The known decay modes are modeled with EVTGEN [40] using branching fractions taken from the Particle Data Group (PDG) [41], the remaining unknown decays from the charmonium states with LUNDCHARM [42], and the cross sections for the open charm final states are cited from [43–47]. The final-state radiation (FSR) from charged final state particles are incorporated with the PHOTOS package [48]. As described in Sec. IV B, some “peaking backgrounds” could pass our selection requirements. MC samples for those processes are generated for the study of distributions and misidentification rates.

#### IV. MEASUREMENTS OF CROSS SECTIONS

For a given c.m. energy  $E_{\text{cm}}$ , the dressed cross sections for  $e^+e^- \rightarrow K^+K^-\pi^+\pi^-(\pi^0)$ ,  $K^+K^-K^+K^-(\pi^0)$ ,  $\pi^+\pi^-\pi^+\pi^-(\pi^0)$ , and  $p\bar{p}\pi^+\pi^-(\pi^0)$  are given by

$$\sigma = \frac{N^{\text{obs}} - N^{\text{bkg}}}{L\epsilon^0\kappa}, \quad (1)$$

where  $N^{\text{obs}}$  is the number of candidate signal events observed in the data sample,  $N^{\text{bkg}}$  is the number of background events,  $L$  is the integrated luminosity of the data collected at  $E_{\text{cm}}$ ,  $\epsilon^0$  is the reconstruction efficiency without considering ISR, and  $\kappa$  is the correction factor describing the effect of ISR [49].

##### A. Selection of signal events

For each channel, all final state particles are reconstructed. To ensure each track originates from the  $e^+e^-$  collision point, the tracks must satisfy  $V_r < 1.0$  cm and  $|V_z| < 10.0$  cm. Here  $V_r$  is the distance between the charged track and the beam axis in the  $r\varphi$  plane, and  $|V_z|$  is the coordinate of the charged particle production point along the beam axis. The polar angles of charged tracks are required to satisfy  $|\cos\theta| < 0.93$ . Exactly four good tracks satisfying these criteria are required.

For the final states with a  $\pi^0$ , we reconstruct  $\pi^0$  candidates through  $\pi^0 \rightarrow \gamma\gamma$ . Showers must have energy greater than 25 MeV in the barrel region ( $|\cos\theta| < 0.80$ ) of the EMC and greater than 50 MeV in the end caps ( $0.86 < |\cos\theta| < 0.92$ ). Showers must have timing within 700 ns of the event start time. For  $K^+K^-\pi^+\pi^-$  and  $K^+K^-\pi^+\pi^-\pi^0$  final states, we apply particle identification based on  $dE/dx$  and TOF measurements to reduce multiple combinations of particle hypotheses within candidate events. We require the kaon candidates have a higher probability to be kaons than pions. Only pion and kaon hypotheses are compared because these are the most serious sources of misidentification.

A kinematic fit is applied to candidate events. For signal channels without (with) a  $\pi^0$ , we perform a four-constraint (five-constraint) kinematic fit to the known initial

TABLE I. Summary of the cuts applied to the two-body and three-body invariant mass distributions.

Final state	Cut
$e^+e^- \rightarrow K^+K^-\pi^+\pi^-$	$ M_{\pi^+\pi^-} - M_{J/\psi}  > 15 \text{ MeV}/c^2$ $ M_{K^\pm\pi^\mp} - M_D  > 20 \text{ MeV}/c^2$
$e^+e^- \rightarrow \pi^+\pi^-\pi^+\pi^-$	$ M_{\pi^+\pi^-} - M_{J/\psi}  > 15 \text{ MeV}/c^2$ $ M_{\pi^+\pi^-} - M_{\psi(2S)}  > 20 \text{ MeV}/c^2$
$e^+e^- \rightarrow p\bar{p}\pi^+\pi^-$	$ M_{p\bar{p}} - M_{J/\psi}  > 15 \text{ MeV}/c^2$ $ M_{p\bar{p}} - M_{\psi(2S)}  > 20 \text{ MeV}/c^2$
$e^+e^- \rightarrow K^+K^-\pi^+\pi^-\pi^0$	$ M_{K^+K^-} - M_{\chi_{c0}}  > 50 \text{ MeV}/c^2$ $ M_{K^\pm\pi^\mp} - M_D  > 20 \text{ MeV}/c^2$ $ M_{\pi^+\pi^-} - M_{K_s^0}  > 30 \text{ MeV}/c^2$
$e^+e^- \rightarrow \pi^+\pi^-\pi^+\pi^-\pi^0$	$ M_{\pi^+\pi^-} - M_{J/\psi}  > 15 \text{ MeV}/c^2$ $ M_{\pi^+\pi^-} - M_{\chi_{c0}}  > 50 \text{ MeV}/c^2$ $ M_{\pi^+\pi^-} - M_{K_s^0}  > 30 \text{ MeV}/c^2$ $ M_{\pi^+\pi^-\pi^0} - M_{J/\psi}  > 15 \text{ MeV}/c^2$

four-momentum (and  $\pi^0$  mass). We require that the  $\chi^2$  of the kinematic fit is less than 50. If more than one combination per mode satisfies the above selection requirements, only the one with the least  $\chi^2$  is kept.

Background events from the two-photon processes  $e^+e^- \rightarrow e^+e^- + \text{hadrons}$ , together with  $e^+e^- \rightarrow (\gamma)e^+e^-$  are rejected using the ratio  $E_{\text{EMC}}/p$  for each charged track, where  $E_{\text{EMC}}$  is the energy deposited in the EMC and  $p$  is the momentum of the charged track. For candidate events from the processes  $e^+e^- \rightarrow K^+K^-\pi^+\pi^-$ ,  $K^+K^-K^+K^-$ ,  $\pi^+\pi^-\pi^+\pi^-$  and  $\pi^+\pi^-\pi^+\pi^-\pi^0$ , it is required that each track have an  $E_{\text{EMC}}/p$  less than 0.8. The gamma conversion backgrounds are rejected by applying cuts to  $\theta_{\pi^+\pi^-}$ , which is the opening angle between all  $\pi^+\pi^-$  pairs. For candidates events of  $e^+e^- \rightarrow K^+K^-\pi^+\pi^-$ ,  $\pi^+\pi^-\pi^+\pi^-$  and  $p\bar{p}\pi^+\pi^-$ , it is required that  $\cos\theta_{\pi^+\pi^-} < 0.9$ . To reduce systematic uncertainty, the distributions of  $E_{\text{EMC}}/p$  and  $\cos\theta_{\pi^+\pi^-}$  from MC samples have been corrected according to data. Here the MC sample is the PHSP MC reweighted with the amplitude analysis results, which will be described in Sec. IV C. The correction factor is determined using a control sample of the signal process. The distributions of  $E_{\text{EMC}}/p$  and  $\theta_{\pi^+\pi^-}$  from all the other channels are checked as well but no obvious backgrounds are found.

We next check for backgrounds in two-body and three-body invariant mass distributions within each final state. There are obvious backgrounds from  $J/\psi$ ,  $\psi(2S)$ ,  $\chi_c$ ,  $D$  and  $K_s^0$  decays. Those backgrounds are removed with the requirements summarized in Table I.

##### B. Background study

Our selected candidate events include both signal events as well as misidentified background events from other processes. Potential background sources include  $e^+e^- \rightarrow (\gamma)e^+e^-$ ,  $e^+e^- \rightarrow (\gamma)\mu^+\mu^-$ ,  $e^+e^- \rightarrow (\gamma)\tau^+\tau^-$ ,

$e^+e^- \rightarrow$  hadrons. To study such backgrounds, we analyzed the inclusive MC generated at 4.226 GeV using the same selection requirements for data. Such studies show that there are two types of background. The first is from  $D$  and  $J/\psi$  decays, where the final states are the same as the signal channel. For example,  $e^+e^- \rightarrow D^0\bar{D}^0, D^0 \rightarrow K^-\pi^+, \bar{D}^0 \rightarrow K^+\pi^-$  is background process for  $e^+e^- \rightarrow K^+K^-\pi^+\pi^-$ . Although we have applied requirements to veto that background, there are still residual events left. The distributions of the  $\chi^2$  from the kinematic fit are almost the same as those for the signal events; we call this the “peaking background.” The second type of background is from processes where the final states are different from the signal channel. In this case, the  $\chi^2$  distributions of these processes are also different than signal;

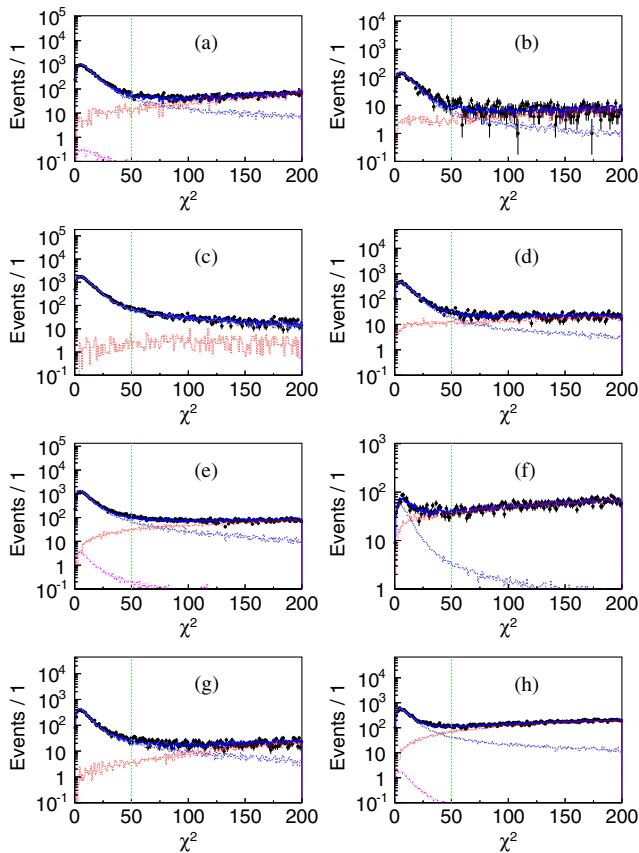

FIG. 1. The fit to the  $\chi^2$  from the kinematic fit for (a)  $e^+e^- \rightarrow K^+K^-\pi^+\pi^-$ , (b)  $e^+e^- \rightarrow K^+K^-K^+K^-$ , (c)  $e^+e^- \rightarrow \pi^+\pi^-\pi^+\pi^-$ , (d)  $e^+e^- \rightarrow p\bar{p}\pi^+\pi^-$ , (e)  $e^+e^- \rightarrow K^+K^-\pi^+\pi^-\pi^0$ , (f)  $e^+e^- \rightarrow K^+K^-K^+K^-\pi^0$ , (g)  $e^+e^- \rightarrow \pi^+\pi^-\pi^+\pi^-\pi^0$ , and (h)  $e^+e^- \rightarrow p\bar{p}\pi^+\pi^-\pi^0$  at 4.226 GeV. To evaluate the goodness of those fits, we check the  $\chi^2/\text{ndf}$  of those plots, which are 1.75, 1.16, 1.54, 1.18, 1.59, 1.03, 1.36, and 1.50, respectively. The number of background in  $\chi^2$  signal region, which would be subtracted when calculating the cross section, is obtained from this fit. The blue dashed line shows the distribution from signal MC. The pink dash-dotted lines and red dotted lines show the distribution from peaking and nonpeaking backgrounds, respectively. The green dashed line shows the signal region.

we refer to this background as “nonpeaking background.” To estimate the number of nonpeaking background events, a fit is performed to the  $\chi^2$  from the kinematic fit.

Figure 1 shows the fit to the  $\chi^2$  at 4.226 GeV. The signal shape is from signal MC simulation. The distribution of peaking background is from peaking background MC, the number of which is fixed according to previously measured cross sections [50,51] and reconstruction efficiency determined with MC simulation. The contamination rates from peaking backgrounds are less than 0.8% for all signal final states. The shape of the nonpeaking background is obtained from inclusive background MC samples, and the number of nonpeaking background is allowed to float. From this fit, the number of nonpeaking background events in the signal region ( $\chi^2 < 50$ ) is obtained.

### C. Reconstruction efficiency

In the two-body and three-body invariant mass distributions, there are many intermediate states, such as  $\rho$ ,  $\omega$ ,  $\phi$ ,  $\eta$ ,  $a$ ,  $b$ ,  $f$ ,  $K^*$ ,  $N$ ,  $\Lambda$ ,  $\Delta$ . Final states with these various

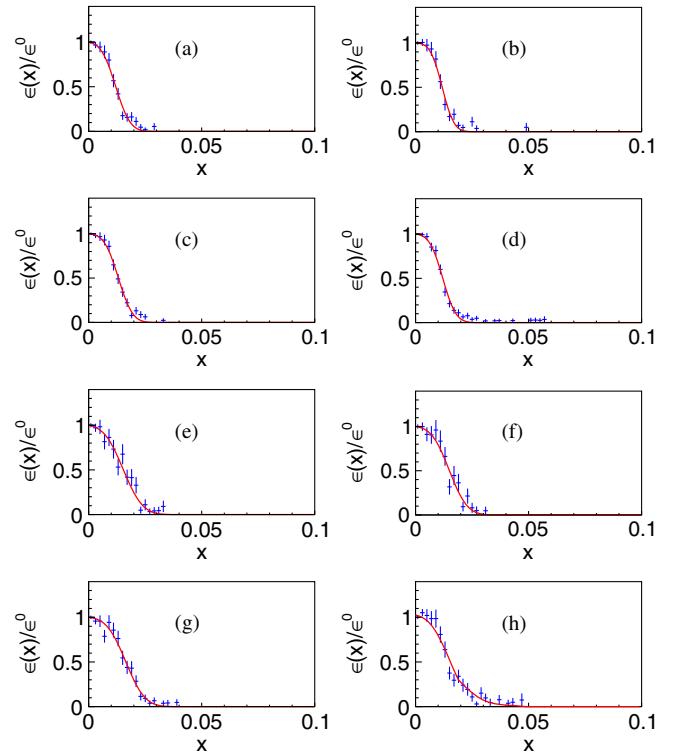

FIG. 2. The distribution of  $e(x)/e^0$  for (a)  $e^+e^- \rightarrow K^+K^-\pi^+\pi^-$ , (b)  $e^+e^- \rightarrow K^+K^-K^+K^-$ , (c)  $e^+e^- \rightarrow \pi^+\pi^-\pi^+\pi^-$ , (d)  $e^+e^- \rightarrow p\bar{p}\pi^+\pi^-$ , (e)  $e^+e^- \rightarrow K^+K^-\pi^+\pi^-\pi^0$ , (f)  $e^+e^- \rightarrow K^+K^-K^+K^-\pi^0$ , (g)  $e^+e^- \rightarrow \pi^+\pi^-\pi^+\pi^-\pi^0$  and (h)  $e^+e^- \rightarrow p\bar{p}\pi^+\pi^-\pi^0$  at 4.226 GeV. Points with error bars show the  $e(x)/e^0$  determined using signal MC. The red lines show the fit to the distributions. To evaluate the goodness of those fits, we check the  $\chi^2/\text{ndf}$  of those plots, which are 0.67, 1.13, 1.13, 1.30, 0.64, 1.00, 0.60, and 1.56, respectively.

TABLE II. Summary of the c.m. energies and luminosities of datasets, together with the dressed cross sections for  $e^+e^- \rightarrow K^+K^-\pi^+\pi^-(\pi^0)$ ,  $K^+K^-K^+K^-(\pi^0)$ ,  $\pi^+\pi^-\pi^+\pi^-(\pi^0)$ ,  $p\bar{p}\pi^+\pi^-(\pi^0)$  in the energy region between 3.773 and 4.600 GeV. Errors are statistical only.

resonant intermediate states are also signal processes. To determine the reconstruction efficiency more accurately, we need to consider the relative contributions from those processes. Using the AMPTOOLS [52,53] package, amplitude analyses are performed to some of the large data samples (at 3.773, 4.008, 4.226, 4.258, 4.358, 4.416 and 4.600 GeV), together with MC samples generated at the same energy points. Relative amplitudes of different intermediate states yielding each final state are determined from these analyses. We use the ratios obtained from

4.226 GeV in the determination of reconstruction efficiencies for all the energy points. Differences in these amplitude ratios are considered as a source of systematic error, based on possible small variations from other datasets with large statistics.

Weights are assigned to PHSP signal MC event by event according to ratios of squared amplitudes. Applying the same selection requirements as used in data analysis, the MC efficiencies  $\epsilon^0$  are determined from signal MC samples without ISR.

## D. ISR corrections

The ISR effect is considered using the factor  $\kappa$ , which is defined as

$$\kappa = \frac{1}{\sigma^0 \epsilon^0} \int \sigma(s') \epsilon(x) W(x, s) dx, \quad (2)$$

where  $s = E_{\text{cm}}^2$ ,  $x$  is the radiative photon energy fraction,  $s' = s(1-x)$ ,  $W(x, s)$  is the radiator function [49] and  $\sigma^0$  is the dressed cross section corresponding to  $x = 0$ .

Applying the same selection requirements as those applied to the data,  $\epsilon(x)$  is determined by analyzing signal MC samples with ISR. The distribution of  $\epsilon(x)/\epsilon^0$  for every channel at 4.226 GeV, together with the fit to error function, is shown in Fig. 2. Inserting  $\epsilon(x)$  into Eq. (2), we calculated the factor  $\kappa$ .

## E. Dressed cross section

Inserting the number of observed signal events, the number of peaking and nonpeaking backgrounds events, the luminosity of the data sample, the reconstruction efficiency, and the radiative correction factor into Eq. (1), we obtain the dressed cross section for  $e^+e^- \rightarrow K^+K^-\pi^+\pi^-(\pi^0)$ ,  $K^+K^-K^+K^-(\pi^0)$ ,  $\pi^+\pi^-\pi^+\pi^-(\pi^0)$  and  $p\bar{p}\pi^+\pi^-(\pi^0)$  at each energy point. These cross sections are summarized in Table II, where the errors are statistical only.

## F. Analysis of dressed cross section

A least  $\chi^2$  fit is applied to those dressed cross sections. The function to be minimized is

$$\chi^2 = \sum_{i=1}^N \left( \frac{\sigma(E_{\text{cm}}) - \sigma^{\text{expected}}(E_{\text{cm}})}{\Delta_{\sigma(E_{\text{cm}})}} \right)^2, \quad (3)$$

where  $\sigma^{\text{expected}}(E_{\text{cm}})$  is the theoretically expected dressed cross section,  $\sigma(E_{\text{cm}})$  is the measured value of the dressed cross section with combined statistical and uncorrelated systematic error  $\Delta_{\sigma(E_{\text{cm}})}$  at the  $i$ th energy point, and  $N$  is the number of data samples collected at different energy points.

First, we consider the expected dressed cross section of the continuum process:

$$\sigma_{\text{cont}}^{\text{expected}} = |A_{\text{cont}}|^2, \quad (4)$$

where  $A_{\text{cont}}$  is the amplitude of the continuum process,

$$A_{\text{cont}} = \sqrt{\frac{f_{\text{cont}}}{(E_{\text{cm}}/4.226 \text{ GeV})^n}}, \quad (5)$$

and where  $E_{\text{cm}}$  is the c.m. energy,  $f_{\text{cont}}$  and  $n$  are floating parameters in the fit. Results from these fits, which only

consider the contribution from the continuum process, are shown in Fig. 3 and listed in Table III.

### 1. Branching fraction of $\psi(4040) \rightarrow \pi^+\pi^-\pi^+\pi^-\pi^0$

For the dressed cross section of  $e^+e^- \rightarrow \pi^+\pi^-\pi^+\pi^-\pi^0$ , we also constructed a fit amplitude including a contribution from  $\psi(4040)$  decay:

$$\sigma_{\text{cont}+\psi(4040)}^{\text{expected}} = |A_{\text{cont}} + A_{\psi(4040)} e^{i\phi}|^2, \quad (6)$$

where  $\phi$  is the relative phase, and  $A_{\psi(4040)}$  is a Breit-Wigner for the production of the  $\psi(4040)$ :

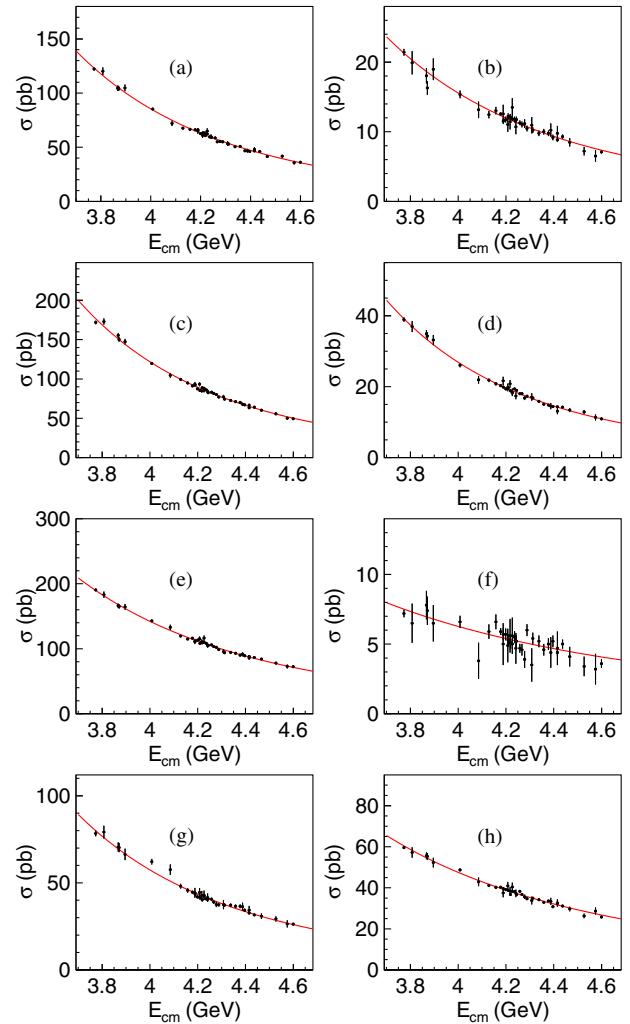

FIG. 3. Fits to dressed cross sections for (a)  $e^+e^- \rightarrow K^+K^-\pi^+\pi^-$ , (b)  $e^+e^- \rightarrow K^+K^-K^+K^-$ , (c)  $e^+e^- \rightarrow \pi^+\pi^-\pi^+\pi^-$ , (d)  $e^+e^- \rightarrow p\bar{p}\pi^+\pi^-$ , (e)  $e^+e^- \rightarrow K^+K^-\pi^+\pi^-\pi^0$ , (f)  $e^+e^- \rightarrow K^+K^-K^+K^-\pi^0$ , (g)  $e^+e^- \rightarrow \pi^+\pi^-\pi^+\pi^-\pi^0$  and (h)  $e^+e^- \rightarrow p\bar{p}\pi^+\pi^-\pi^0$  only considering contribution from continuum process. Points with error bars show the measured dressed cross sections. The red lines show the fit results.

TABLE III. Summary of fit results considering only the contribution from the continuum process. The first errors are statistical and the second systematic.

Final state	$\chi^2/\text{ndf}$	$f_{\text{cont}}$ (GeV $^n$ /pb)	$n$
$K^+K^-\pi^+\pi^-$	1.24	$60.65 \pm 0.19 \pm 2.97$	$6.24 \pm 0.07 \pm 0.01$
$K^+K^-K^+K^-$	0.78	$11.59 \pm 0.08 \pm 0.57$	$5.36 \pm 0.14 \pm 0.01$
$\pi^+\pi^-\pi^+\pi^-$	1.11	$85.94 \pm 0.25 \pm 4.38$	$6.36 \pm 0.06 \pm 0.01$
$p\bar{p}\pi^+\pi^-$	0.89	$18.88 \pm 0.08 \pm 0.83$	$6.43 \pm 0.09 \pm 0.01$
$K^+K^-\pi^+\pi^-\pi^0$	1.11	$108.72 \pm 0.25 \pm 5.11$	$4.97 \pm 0.05 \pm 0.01$
$K^+K^-K^+K^-\pi^0$	1.07	$5.29 \pm 0.07 \pm 0.33$	$3.08 \pm 0.26 \pm 0.01$
$\pi^+\pi^-\pi^+\pi^-\pi^0$	1.06	$42.44 \pm 0.21 \pm 2.37$	$5.54 \pm 0.11 \pm 0.01$
$p\bar{p}\pi^+\pi^-\pi^0$	1.23	$37.91 \pm 0.12 \pm 1.74$	$4.11 \pm 0.07 \pm 0.01$

$$A_{\psi(4040)} = \frac{\sqrt{12\pi\Gamma_{\psi(4040)}^{ee}\Gamma_{\psi(4040)}^{\text{total}}\text{BF}(\psi(4040) \rightarrow \pi^+\pi^-\pi^+\pi^-\pi^0)}}{(E_{\text{cm}}^2 - M_{\psi(4040)}^2) + i\Gamma_{\psi(4040)}^{\text{total}}M_{\psi(4040)}}, \quad (7)$$

where  $M_{\psi(4040)}$ ,  $\Gamma_{\psi(4040)}^{\text{total}}$  and  $\Gamma_{\psi(4040)}^{ee}$  are the mass, the total width, and the leptonic width of the  $\psi(4040)$ . In this fit, the values of  $\Gamma_{\psi(4040)}^{\text{total}}$  and  $\Gamma_{\psi(4040)}^{ee}$  are fixed according to the PDG listings [41]. The fit has two solutions with equally good fit quality, while the phases and the branching fractions are different. The fit is shown in Fig. 4, and the fit parameters are listed in Table IV.

Compared to the previous fit result listed in Table III, the number of free parameters is increased by 2 [ $\text{BF}(\psi(4040) \rightarrow \pi^+\pi^-\pi^+\pi^-\pi^0)$  and  $\phi$ ] and the value of the  $\chi^2$  is reduced by 16.0, which corresponds to a statistical significance of  $3.6\sigma$ .

## 2. Upper limits of $Y(4230)$ decays

Furthermore, we search for decays of the charmonium-like resonance  $Y(4230)$  into those same final states, and

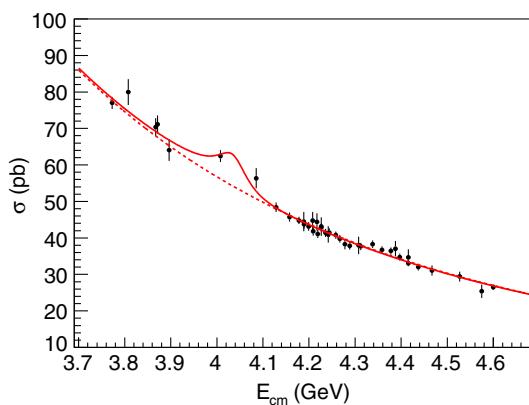

FIG. 4. Fit to dressed cross sections for  $e^+e^- \rightarrow \pi^+\pi^-\pi^+\pi^-\pi^0$  considering contribution from continuum process,  $\psi(4040)$  decay and interference between them. Points with error bars show the measured dressed cross sections. The red curve shows the fit result. The dashed red curve shows the contribution from continuum process.

TABLE IV. Summary of fit results for the  $\pi^+\pi^-\pi^+\pi^-\pi^0$  final state, including the continuum process,  $\psi(4040)$  decay, and interference between them. The first errors are statistical and the second systematic.

corresponding upper limits are provided since no clear signal is observed. The expected dressed cross sections are constructed as

$$\sigma_{\text{cont}(\psi(4040))+Y(4230)}^{\text{expected}} = |A_{\text{cont}}(+A_{\psi(4040)}e^{i\phi}) + A_{Y(4230)}e^{i\phi'}|^2, \quad (8)$$

where  $\phi$  and  $\phi'$  are the relative phases,  $A_{\psi(4040)}$  and  $A_{Y(4230)}$  are Breit-Wigners for  $\psi(4040)$  and  $Y(4230)$ , respectively. The resulting likelihood distribution as a function of the  $Y(4230)$  yield is used to get the upper limits at 90% confidence level for  $\text{BF}(Y(4230) \rightarrow \text{Light Hadrons})$ . The integral from zero to the upper limit contains 90% of the area of the likelihood distribution. The original likelihood distributions are convolved with a Gaussian function, whose width is the systematic uncertainty of the cross section. To estimate the systematic uncertainties in the upper limits of  $Y(4230)$  decays, we have used values of  $M_{Y(4230)}$  and  $\Gamma_{Y(4230)}^{\text{total}}$  from different experimental measurements [6–9], and the largest resulting upper limits of  $\text{BF}(Y(4230) \rightarrow \text{Light Hadrons})$  are given in Table V.

## V. SYSTEMATIC UNCERTAINTY

The systematic uncertainties on the cross section measurements mainly come from the uncertainties in tracking,  $\pi^0$  reconstruction, luminosity, fit of  $\chi^2$  distribution,  $E_{\text{EMC}}/p$  cut,  $\cos\theta_{\pi^+\pi^-}$  cut, and efficiency determination.

The uncertainty of the tracking efficiency is 1.0% [54] per track. The uncertainty of  $\pi^0$  reconstruction is 2.0% [55]. The luminosity is measured using Bhabha events, with an uncertainty of 1.0% [36]. To determine the systematic uncertainty due to particle identification (PID) requirements, we selected control samples of  $K^+K^-\pi^+\pi^-$  and  $K^+K^-\pi^+\pi^-\pi^0$  from data and MC. The MC sample is the PHSP MC reweighted according to the amplitude analysis results. The nominal PID requirements are replaced with a tighter cut: for kaon (pion) selection, it is required the probability to be kaon (pion) is greater than the probability to be pion (kaon). By studying the change of efficiencies,

we determine the systematic uncertainty due to PID requirements for  $K^+K^-\pi^+\pi^-$  and  $K^+K^-\pi^+\pi^-\pi^0$  final states are both 0.5%.

The contamination rates from peaking backgrounds are less than 0.8% at all energy points for all signal final states. Those contamination rates are very low, so we neglect the systematic uncertainty from peaking background subtraction. The estimation of nonpeaking background is from the fit to the  $\chi^2$  distribution. To estimate the uncertainty from the fit to the  $\chi^2$  distribution, we refit the  $\chi^2$  distributions by varying the bin size, the fit range, the signal shape and the background shape. The shape of signal MC is determined through MC simulation. In this work, for every candidate event, we select the combination with the least  $\chi^2$ . But it may be the wrong combination, and hence affect the signal shape. So we replace the nominal signal  $\chi^2$  shape with the one from MC truth information, compare with the nominal result, and determine the systematic uncertainty due to the selection of the wrong combination. The helix parameters are used to describe the tracks. To reduce the systematic uncertainty, we corrected the helix parameters from MC samples. We change the helix correction factors by  $\pm 1\sigma$  to determine the systematic uncertainty due to the signal shape. The shape of nonpeaking backgrounds is determined using inclusive MC samples. We replace the shape of the nonpeaking backgrounds by an Argus function and refit the  $\chi^2$  distributions. The difference on the cross sections is taken as the systematic uncertainty. By adding these values in quadrature, we assign the uncertainty associated with the fit, which is dominated by the background shape. The distributions of  $E_{\text{EMC}}/p$  and  $\cos\theta_{\pi^+\pi^-}$  from MC sample have been corrected according to data, which corresponds to correction factors on the reconstruction efficiency. The errors of the correction factors are taken as the systematic uncertainties.

When determining the efficiencies, we applied a AMPTOOLS analysis using data and MC samples at 4.226 GeV, and fixed the model to get efficiencies at every energy point. To estimate the systematic uncertainty, we repeat the process using data and MC samples at 3.773, 4.008, 4.258, 4.358, 4.416 and 4.600 GeV. The maximum

difference in efficiency is taken as the systematic uncertainty. The uncertainty from the efficiency is treated as an uncorrelated uncertainty, which is taken into consideration in the analysis of cross sections.

The values of  $\kappa$  are related to input cross sections, which are obtained from fits. We randomly change the fit parameters according to the covariance matrix from the fit.  $\kappa$  is recalculated according to different cross section parameters. The change in  $\kappa$  is less than 0.025% for all channels, so the uncertainty of  $\kappa$  is negligible.

The systematic uncertainties of the fit parameters, as listed in Tables III and IV, originate from the uncertainty of the c.m. energies, the uncertainty of cross sections, and the uncertainty of  $\psi(4040)$  resonance parameters. The systematic uncertainty originating from c.m. energies is estimated by smearing c.m. energies with a standard deviation of 0.8 MeV [56]. Then we take the maximum difference of the parameters as the systematic uncertainty. Similarly, the systematic uncertainties due to cross sections and  $\psi(4040)$  resonance parameters are estimated by re-obtaining the fit parameters after changing the value of the cross sections and  $\psi(4040)$  resonance parameters by  $\pm 1\sigma$ , respectively. Finally, we assign the total systematic uncertainty by adding these values in quadrature.

## VI. SUMMARY

The dressed cross sections for the processes  $e^+e^- \rightarrow K^+K^-\pi^+\pi^-(\pi^0)$ ,  $K^+K^-\pi^+\pi^-(\pi^0)$ ,  $\pi^+\pi^-\pi^+\pi^-(\pi^0)$ ,  $p\bar{p}\pi^+\pi^-(\pi^0)$  are obtained with data samples collected at 40 energy points from 3.773 to 4.600 GeV. Those cross sections depend on c.m. energy according to  $1/E_{\text{cm}}^n$  and we determine  $n$  for each process. We find evidence of the  $\psi(4040)$  decays to  $\pi^+\pi^-\pi^+\pi^-\pi^0$  with a statistical significance of  $3.6\sigma$ . No obvious  $Y(4230)$  signals are observed, so

we provide upper limits for  $Y(4230)$  decays into those final states at the 90% confidence level.

## ACKNOWLEDGMENTS

The BESIII collaboration thanks the staff of BEPCII and the IHEP computing center for their strong support.
